Abstract: TODO

Keywords: Artificial intelligence, Neural networks,

1. INTRODUCTION

1.1 Background

A Large Language Model (LLM) is neural network model which is capable at working with natural language tasks such as text generation, tmeasurmentext summarization, translation, and more. The novel Transformer architecture proposed in the "Attention Is All You Need" paper [13] has revolutionized the field by introducing more efficient multi-headed self-attention mechanism compared to Recurrent Neural Networks that came before. With the improvements in training times, better parallelization on GPUs and overall quality of output. Following this, OpenAI have used this novel Transformer architecture to design and develop their Generative Pre-Trained Transformer (GPT) LLMs the following years. In particular, the release of GPT-3 in 2020, has sparked a global interest in the continued development of LLMs from various companies such as Meta with LLaMa, Google with Gemma, Antropic with Claude, etc.

The AI researchers at Meta have developed a series of open-weight LLMs called LLaMa, ranging from 7B parameters to 65B parameters [12]. Their paper demonstrates, using various benchmark tests, we can draw a correlation between the increase in LLMs parameters and the scores that it can achieve on various benchmark tests such as HellaSwag [14], WinoGrande [9], ARC [2] and OpenBookQA [7]. There are challenges with regards to the computational requirements necessary for inferencing LLMs, "the compute and memory requirements of state-of-the-art language models have grown by three orders of magnitude in the last three years, and are projected to continue growing far faster than hardware capabilities" [1, p. 97].

Quantization and pruning are some of the strategies that can be used to help reduce computational requirement and memory footprint of LLMs. However applying these strategies often comes at the cost of increasing the LLM Perplexity (PPL), a metric for evaluation the uncertainty of a model in predicting a sequence. Quantization methods involve reducing the numerical precision of the model's weights, allowing 32-bit floating point value to be represented as an 8-bit floating point value or even lower. Popular quantization include GPT-Generated Unified For-

mat (GGUF)[4], Activation-Aware Weight Quantization (AWQ)[5], Vector Post-Training Quantization (VPTQ)[6] and others. Pruning involves removing parts of the model that have little effect on the output, this process could involve removing neurons or entire layers.

1.2 Problem Statement and Motivation

As mentioned in the previous section, the hardware requirements for medium to large sized LLMs make it difficult for consumers or small organisations to run their own local LLMs, often requiring to use third-party providers for access to modern powerful LLMs. This potentially reduces their privacy, security and accessibility, which could be otherwise achieved by running LLMs locally on their own hardware. For large businesses who might already be hosting their own models, this could be an opportunity to potentially reduce their running costs with regards to LLMs.

If in the future, smaller LLMs become more capable than they are today, it stands to reason that their larger counterparts would likewise become more capable. Therefore, finding efficient and cost effective methods of reducing hardware requirements for running large LLMs is holds meaningful significance to this researcher.

1.3 Research Scope and Limitations

This research will be using a select few foundational LLMs for testing and evaluation. The selected LLMs will be Gemma2 9B from Google[10], LLaMa 3.1 from Meta 8B [3] and Qwen2.5 7B from Alibaba[11]. These models were selected due to their research permissive licenses, LLM community popularity and reputability of the companies that have trained them.

The hardware for conducting this research will be limited to a single Nvidia RTX 4090 GPU with 24GB of VRAM, which will be sufficient to run the selected LLMs without any quantization. This will allow the researcher to establish baseline metrics and benchmark scores pre-quantization, which can be used to compare against post-quantized results of the selected LLMs.

The hardware used to demonstrate the effects and performance of LLM quantization will be a single Raspberry Pi 4b, which has quad-core Cortex-A72 @ 1.5GHz CPU and

8GB LPDDR4 RAM [8]. This device was chosen for its limited hardware specifications, that should under normal circumstances be insufficient to run any of the selected LLMs previously mentioned. As such, it qualifies to be a test device for this paper's research and would serve as a baseline for future research evaluating more capable devices.

This research will be limited to exploring Post Training Quantization (PTQ) methods and not Quantization Aware Training (QAT) methods, as the latter requires significant computational resources and time in order to carry out such research. PTQ methods are significantly less computationally intensive to perform on pre-trained LLMs and require less time to quantize LLM weights.

1.4 Research Questions

This paper aims to answer the following Research Questions (RQ):

RQ1: What quantization methods (GGUF, AWQ, VPTQ) are the most effective for reducing selected LLMs' inferencing requirements while retaining most of its output quality?

RQ2: What pruning strategies (block-wise, channel-wise, layer-wise) are the most effective for reducing selected LLMs' inferencing requirements while retaining most of its output quality?

RQ3: Deriving the best performing method (or combination of methods) from the previous questions, what is the best achievable performance of selected LLMs on a Raspberry Pi 4b?

2. PRELIMINARY LITERATURE REVIEW

This section will explore the supporting research literature that will cover the topics of various PTQ methods and pruning methods.
